

Title: Bhoomi: Building a Unified Digital Ecosystem for India's Agricultural Future

R. Sai Rithik Reddy

Pre-Session Policy Assignment

Abstract:

Agriculture remains one of the most important sectors of the Indian economy, supporting millions of livelihoods and contributing significantly to national development. Despite technological advancements, farmers still face several challenges, including fragmented access to information, fluctuating market prices, limited access to experts, and difficulties in connecting directly with buyers. While many digital solutions exist, they often address only one aspect of farming, forcing farmers to rely on multiple platforms for different needs.

The idea behind **Bhoomi – The Modern Farming Platform** emerged from a simple observation: farmers need a single, reliable ecosystem that brings together all essential agricultural services. Bhoomi aims to serve as a comprehensive digital platform where farmers can access weather updates, expert guidance, market insights, government schemes, financial services, farm management tools, and direct market opportunities through one interface.

The policy challenge is not the absence of agricultural technology but the lack of integration between existing services. Farmers frequently spend time navigating different sources to obtain information and support, leading to inefficiencies and missed opportunities. A unified platform can simplify access, improve decision-making, and help farmers respond more effectively to market and environmental conditions.

This paper proposes that governments, agricultural institutions, startups, and Farmer Producer Organizations (FPOs) work together to encourage the adoption of integrated digital farming platforms. Public-private partnerships can help expand digital literacy, improve access to verified agricultural data, and ensure that technology reaches farmers across different regions and scales of operation.

Bhoomi can also strengthen agricultural value chains by creating direct connections between farmers, buyers, input suppliers, and financial institutions. Such integration can improve price transparency, reduce dependency on intermediaries, and enable more efficient movement of agricultural produce. In addition, the platform can support data-driven farming practices by providing timely recommendations that help farmers optimize resources and improve productivity.

The expected outcomes include increased farm profitability, better market access, wider adoption of modern agricultural practices, and greater resilience to climate and market uncertainties. By combining technology, knowledge, and market connectivity,

Bhoomi seeks to contribute to a more productive, sustainable, and inclusive agricultural sector.

As India continues its journey toward digital transformation, integrated platforms like Bhoomi have the potential to become an important part of the country's agricultural infrastructure. By connecting stakeholders across the farming ecosystem, Bhoomi can help create a future where every farmer has access to the tools and opportunities needed to succeed.
